

# Grounding Large Language Models in Reality for Biomedical Information Extraction

J. Harry Caufield  
Lawrence Berkeley National Laboratory  
April 25 2025  
EHLC Webinar

# What will I be talking about?

- Are knowledge harmonization and discovery still jobs for humans?
  - Or is this a problem solved by AI?
- Either way, what tools can help?
- How can we focus on the strengths of AI approaches?
  - How may we complement human knowledge curation with AI rather than competing?

# What will I be talking about?

# Where does knowledge come from?

It's the result of **repeated observations**.

**Learning** from and consistently **recording** these observations is a task in itself, but an **impossible** one at the scale we want.

How may we automate:

- Learning from literature?
- Comparing findings?
- Integrating observations?
  - Across different studies or replicates?
  - Across different knowledge bases?
  - Across different fields and disciplines?
  - Of similar concepts, even when described in different contexts?

# Where does knowledge come from?

## **We need structured data.**

This traditionally requires:

- Consistent data models
- Standards
- Ontologies and controlled vocabularies

They don't do the work of structuring data for us.

For that we need:

- Human domain experts
- Access to data
- Tools (for data, standards, ontologies, ...)

# Where does knowledge come from?

Over the years, tools have included:

- **Rules, regular expressions, and parsers**
- **Rule-based extractors** like SemMedDB
- **Enrichment** of terms and/or annotations, like MELODI
- **Neural networks** for Natural Language Processing (e.g., LSTMs)
- Foundational **language models** (e.g., BERT)
- **Multi-task** learning (MTL) approaches

*More rule-based*

*More statistical*

Each method may still be effective for some use cases!

# What are LLMs, anyway?

$$P(S) = P(\text{Where}) \times P(\text{are} \mid \text{Where}) \times P(\text{we} \mid \text{Where are}) \times P(\text{going} \mid \text{Where are we})$$

Input sizes:  
GPT-3: ~570 GB  
GPT-4: ~50 TB

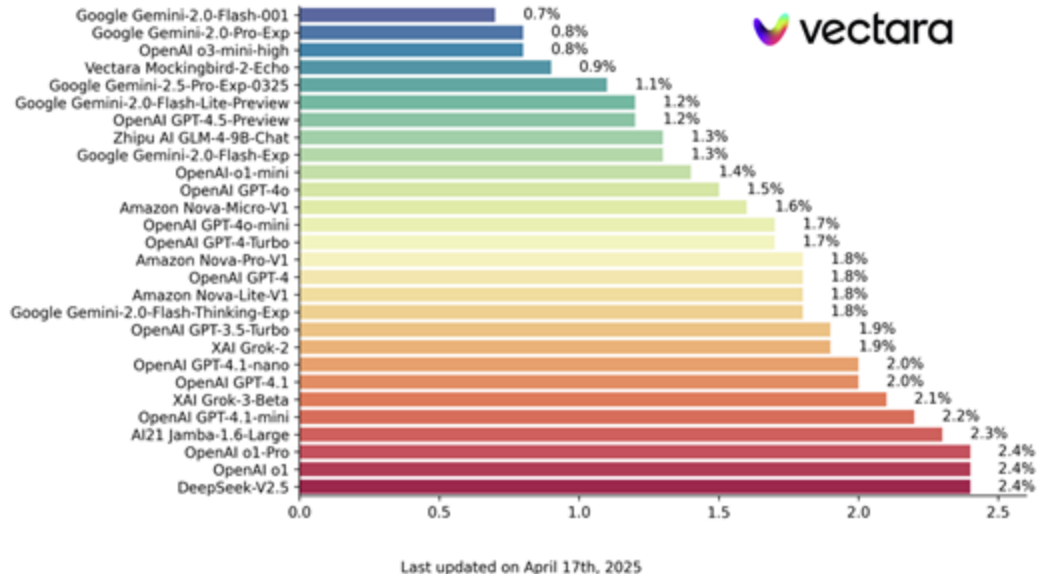

Figures adapted from Huyen (2019) article in *The Gradient*  
(<https://thegradient.pub/understanding-evaluation-metrics-for-language-models/>)  
and Clusmann et al. (2023) *Communications Medicine*

# How often do LLMs fabricate knowledge?

Hallucination Rates for Top 25 LLMs

## Hallucinations (AKA confabulations)

Any output that looks believable but has no basis in reality (or only partial basis).

LLMs are grounded in **language**, not **fact**, so this is to be expected!

This has improved over time with newer models, but is still present.

Using **information from beyond the model** (retrieval augmented generation, or RAG) helps - especially as part of task-specific **agents**.

(Note: this evaluation is based on document summarization, and doesn't account for summary quality.)

<https://github.com/vectara/hallucination-leaderboard>

# Can LLMs assign identifiers correctly?

If we ask GPT-4o: *Please provide the corresponding identifier from the Gene Ontology for each of the following terms.*

And then specify the desired format along with a list of terms...

- >90% of the results are likely to be incorrect in some way.
- This happens with other ontologies as well.
- Also occurs with integrated web search (but search helps!)
- This is not a core strength of LLMs.

```
id: GO:0090729 label: ectopic germ cell programmed cell death

# Can we use LLMs to get structured data?

Can LLMs reliably **translate** unstructured scientific data directly into **knowledge**?

What if:

- We have specific **schemas** or data **models** we want to adhere to
- We need to link to external **unique identifiers**
  - And, ideally, not generate incorrect identifiers
- We want to ask **questions** about ontologies, sources, or both, in **natural language**

# Can we use LLMs to get structured data?

doi: 10.1016/j.ijheh.2024.114333

Effect modification of associations between prenatal air pollution and current asthma at age 8-9 by child sex, prenatal environmental tobacco smoke exposure, and maternal history of asthma. Risk ratios for current asthma and corresponding 95% confidence intervals are shown for association with NO<sub>2</sub> in the first column (panels A, D, and G), O<sub>3</sub> in the second column (panels B, E, and H), and PM<sub>2.5</sub> in the third column (panels C, F, and I). Estimate were reported per 5 ppb NO<sub>2</sub>, 5 ppb O<sub>3</sub>, and 2 µg/m<sup>3</sup> PM<sub>2.5</sub>. All models are adjusted for child age, sex, study site, birth year, maternal education, household income, household count, maternal race, maternal smoking during pregnancy, maternal history of asthma, and Neighborhood Deprivation Index, as well as a product term between the air pollutant exposure and effect modifier of interest. P-values for the product in interaction term are included at the top of each panel. In the first row (panels A-C), sex-specific effect estimates are shown for models including the full analytic sample (N = 1279). No evidence of effect modification by child sex was observed (all p-interaction > 0.05). In the second row (panels D-F), effect estimates are shown among those with maternal history of asthma and those without maternal history of asthma for models including the full analytic sample (N = 1279). For NO<sub>2</sub> and PM<sub>2.5</sub>, those without maternal history of asthma tended to have higher risk ratios than among those with a maternal history of asthma (e.g., p-value for interaction of NO<sub>2</sub> in the 24-36 week window and maternal asthma = 0.03), though confidence intervals for strata-specific risk ratios all include the null. In the third row (panels G-I), effect estimates are shown for associations in a post-hoc analysis among those with high versus low environmental tobacco smoke (ETS) exposure, when the sample was restricted to non-smokers (N = 1155). High ETS was defined as participants with a urinary cotinine value in the highest quartile of the sample (>14.3 ng/mL) and low ETS was defined as participants with a urinary cotinine value in the lowest three quartiles (≤14.3 ng/mL). No effect modification by ETS was observed (all p-interaction > 0.05).

# Can we use LLMs to get structured data?

**Yes, back to structure again:** we need a consistent data model, like **Biolink**

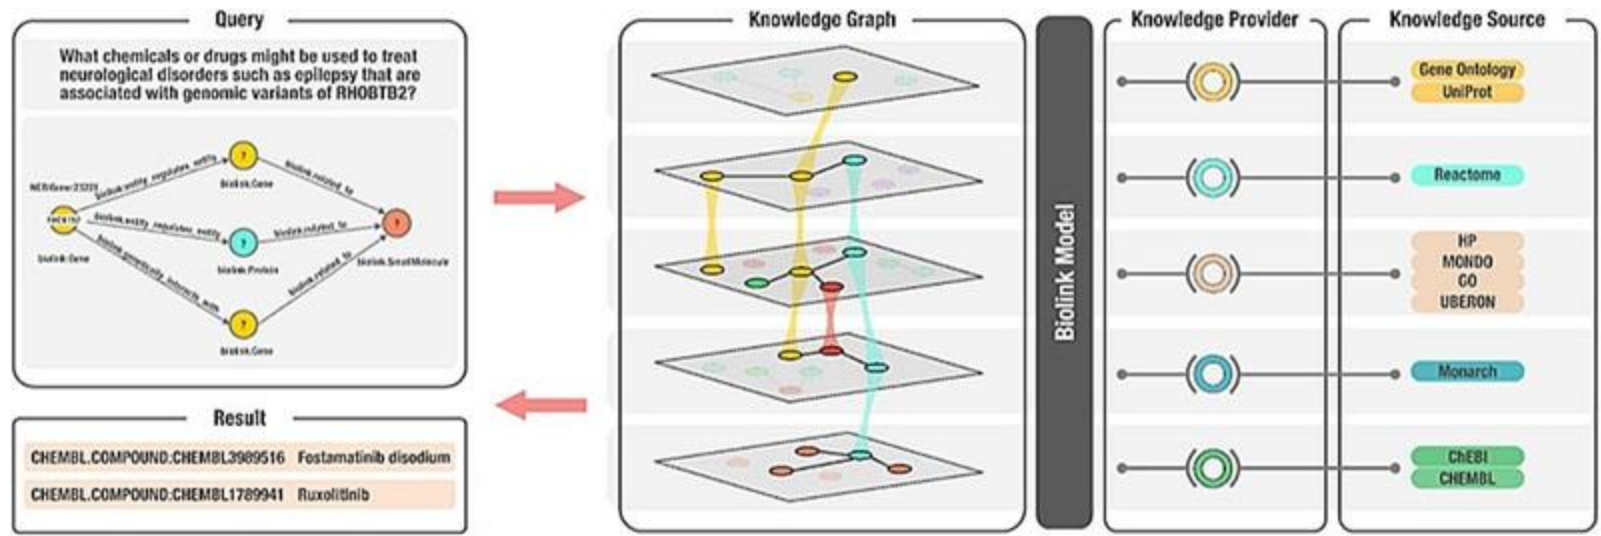

Figure from Unni and Moxon et al. (2022) *Clinical and Translational Science*

# Can we use LLMs to get structured data?

The goal is often to create relationships to include in knowledge graphs.

Our framework for this is **KG-Hub**

See [kg-hub.org](https://kg-hub.org)

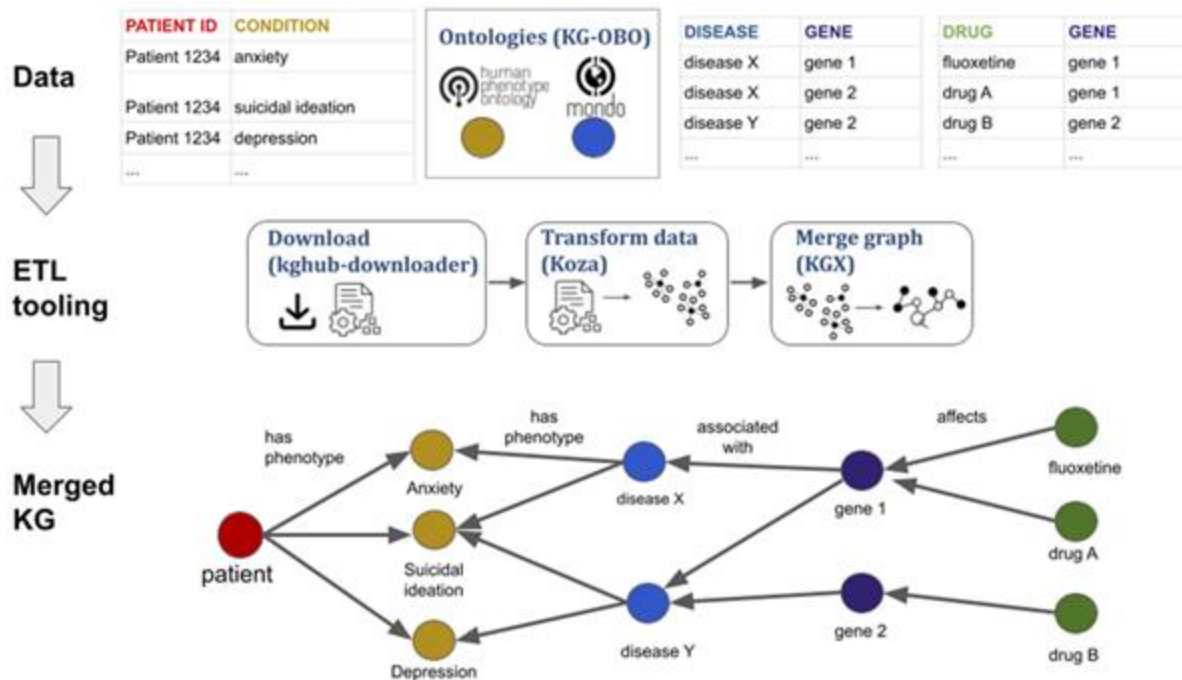

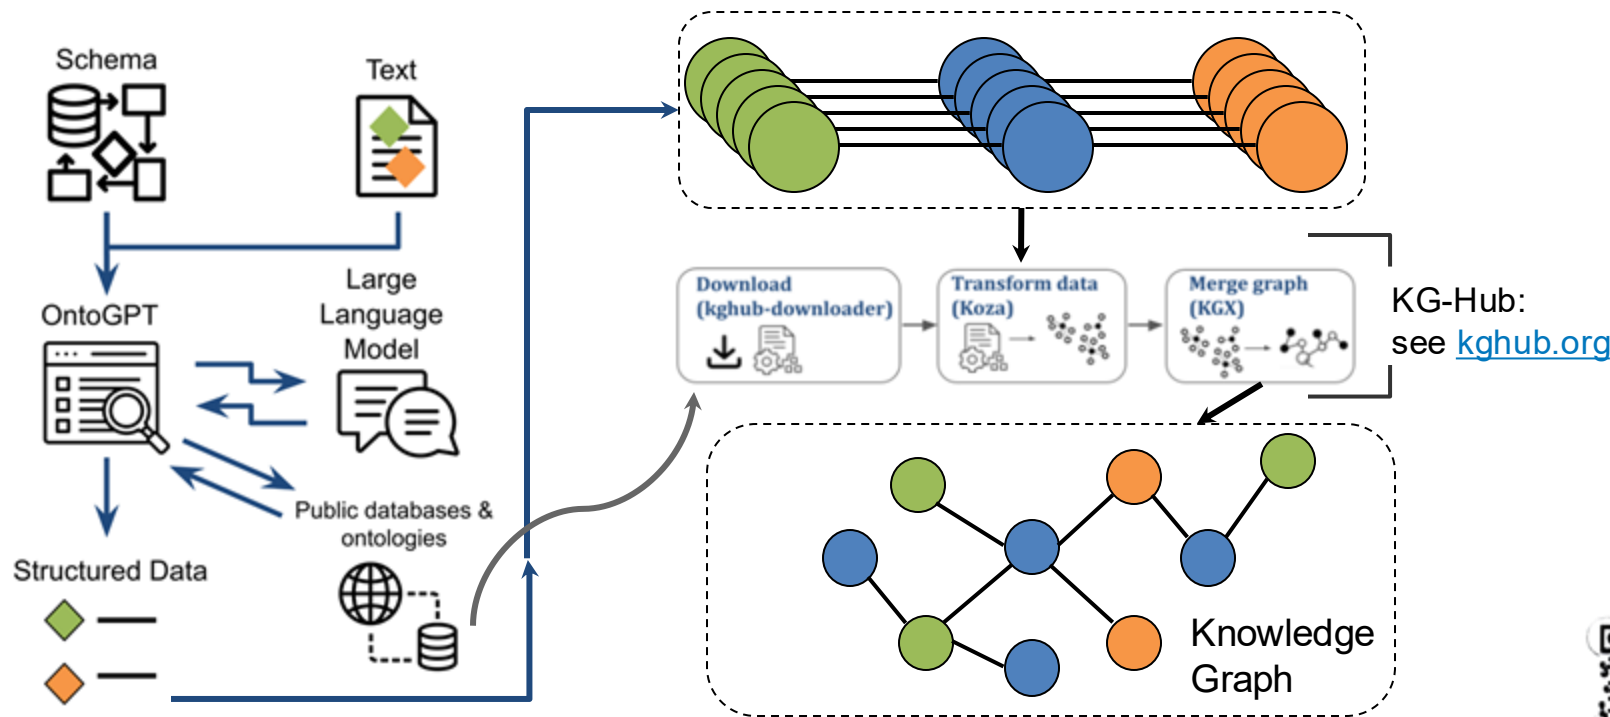

Figure from Caufield et al. (2023) *Bioinformatics*

# Can we use LLMs to get structured data?

See <https://arxiv.org/abs/2304.02711> and <https://github.com/monarch-initiative/ontogpt>

# Can we use LLMs to get structured data?

Other recent OntoGPT applications:

- Medical Action Ontology (MaXO) extraction
- Micronutrient Information Center knowledge extraction (for Monarch Knowledge Graph)
- Pathology report summarization and categorization
- Phenopacket extraction
- Malnutrition prediction in pediatric oncology patients
- Harmonizing environmental science data sets (e.g. in [ESS-DIVE](#))

See Niyonkuru et al. (2024)  
medRxiv

Oregon State  
University

Linus Pauling Institute » Micronutrient Information Center

**ESS-DIVE**  
Deep Insight for Earth Science Data

# Can we use LLMs to get structured data?

Goal: identify candidate annotations for the Medical Action Ontology (MAxO).

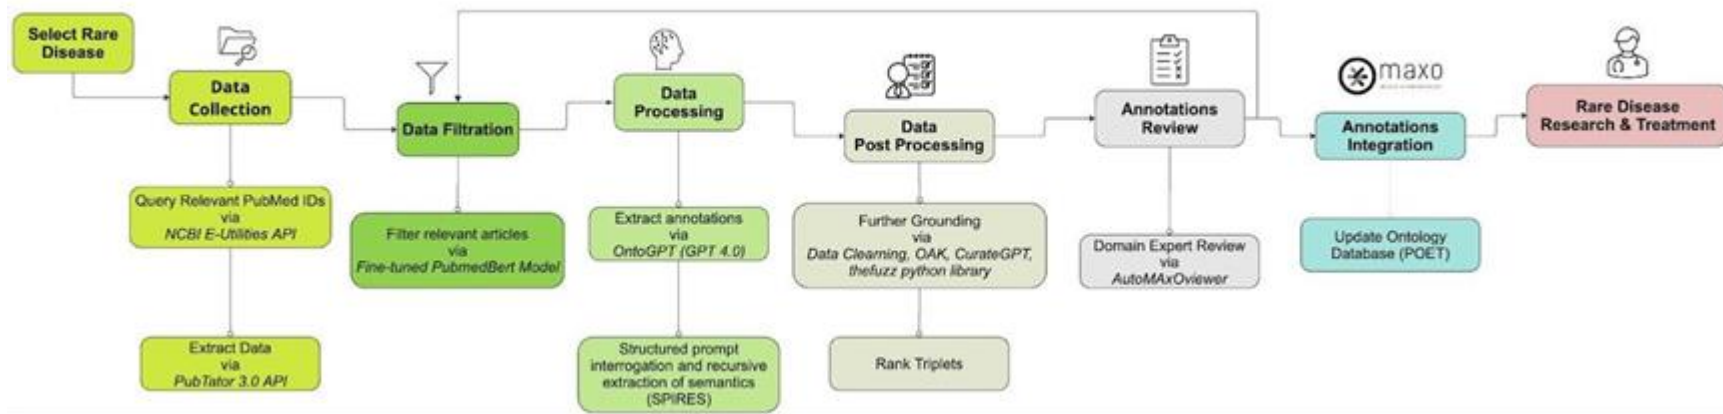

e.g.,

Medical Action: copper chelator agent therapy [MAXO:0001224]

Relationship: PREVENTS

Phenotype: Cirrhosis [HP:0001394]

Disease: Wilson disease Anemia [MONDO:0010200]

Niyonkuru et al. (2024) medRxiv

# Can we use LLMs to get structured data?

Goal: extract structured, knowledge graph-ready relationships from the Micronutrient Information Center, including:

Nutrient to disease

Nutrient to phenotype

Nutrient to biological process

Nutrient to health status of

a body part or system

Nutrient to food source

Nutrient to nutrient

Ask me anything (within the scope of ont\_cob)!

What is a good term to describe a cell?

Detail  
10

☐ Expand query

Examples:

► Details

Chat

A good term to describe a cell would be a "cellular anatomical entity." According to Reference 1, a cellular anatomical entity is a part of a cellular organism with granularity above the level of a protein complex but below that of an anatomical system. This term can include both immaterial and material entities, capturing the complex structure and function of a cell as a component of a larger biological system [1](#).

A nucleic acid chain is a molecule.

Detail

1.0

030

CiteSeek

The evidence to support that a nucleic acid chain is a molecule can be found in Reference 1. According to the definition provided in Reference 1, a "nucleic acid chain" is a molecule that consists of nucleotides linked by phosphodiester bonds or derivatives of such bonds. Furthermore, it is noted in the relationships section of Reference 1 that a nucleic acid chain is a subclass of a "Molecule" [1](#).

## References

### Reference 1

A nucleic acid chain is a molecule.

Detail 1.0

CiteSeek

A nucleic acid chain is a molecule composed of nucleotide monomers linked by phosphodiester bonds, and it plays a crucial role in the storage and transmission of genetic information. Several references from the provided list offer evidence supporting this:

- Reference 4 discusses how Watson and Crick's work in 1953 led to the understanding of DNA's double-helix structure, which is made up of nucleic acid chains that contain genetic information [4](#).
- Reference 9 explores the role of nucleic acids in early life, highlighting their function in genetic information storage and catalytic activities, suggesting that they are essential molecules in the RNA world hypothesis, where RNA acted as both genetic material and a catalyst [9](#).

## References

### Reference 4

```
id: PMID:23622233
title: '1953: when genes became "information",'
abstract: In 1953, Watson and Crick not only described the double-helix structure of DNA, but also embraced the idea that genes contained a code that expresses in and thereby changed our view of life. This article traces how these ideas entered biological thinking and highlights the connections between different branches of science at the time, exploring the power of metaphor in science.
```

### Reference 9

```
id: PMID:29233216
title: 'Nucleic acids: function and potential for abiogenesis.'
abstract: The emergence of functional cooperation between the three main classes of biomolecules - nucleic acids, peptides and lipids - defines life at the molecular level. However, how such mutually interdependent molecular systems emerged from prebiotic chemistry remains a mystery. A key hypothesis, formulated by Crick, Orgel and Woese over 40 years ago, posits that early life must have been simpler. Specifically, it proposed that an early primordial biology lacked proteins and DNA but instead relied on RNA as the key biopolymer responsible not just for genetic information

The  
talisman  
agent in  
use

Specific **agents** for specific **tasks**, on the command line or in a graphical interface.

A task may involve:

- Domain knowledge
  - e.g., The LD50 of arsenic is ~1 mg/kg
- Technical knowledge
  - e.g., X tool may be used for Y
- Knowledge about a specific resource or study
  - e.g., there is a term in ENVO for “industrial wastewater”

# Summary

- LLMs are improving, but still struggle with grounding in reality.
- Human-in-the-loop curation is still essential.

- Tools like OntoGPT and CurateGPT leverage LLMs to extract structured data.
- Specific curation tasks can be performed by different Aurelian agents.
